Strzemski M. Typology of Highland Forest Soils.

„Problem typologii górskich gleb leśnych". Sylwan. No. 1, 1953, pp. 3—11.

A short sketch of the typology of forest soils in the middle European mountains, and an outline of their origin. Discussion is devoted to the opinions of scientists concerning the forming of podsol and brown type soils. Extensive analysis is reported of the causes which check the podsolization process in mountain soils, even under coniferous tree stands: the incline of the terrain is thought to be the chief cause. It is proposed to differentiate three types of mountain soil: brown proper, pseudo-brown and podsols proper, but the view is also taken that a substitute should be found for the expression „pseudo-brown soils".

/ Geochemistry and veterinary medicine. M. Strzemski. *Med. Weterynar.* (Poland) 9, 123(1953); ~~*Veterinarmedizin*~~ *zin* 7, 8 9(1951).—Mineral deficiencies are the cause of many diseases. Cu occurs in the soil, mostly in form of carbonates (I) or oxides (II) and is lacking in peat and sand soils. Zn occurs in soil in form of I, II, or silicates; in CaO soils, Zn is often deficient in plants. Sandy soils are deficient in Mn, heavy loam soils are rich in it. F occurs in many phosphates, especially in soils which were formed from cryst. rocks. Br forms sol. K compds. and occurs in underground water. Iodine behaves like Br and occurs also in the atm. Co occurs often with Fe and Mn, especially in heavy soils. Rudolph Seiden

✓Detailed inventory of manganese in Kielce voivodship soils of the pre-fourth-Ice-Age period. M. Strzemski and Z. Gawęda. *Roczniki Nauk Rolniczych* 70A, No. 1, 17-24 (1954).—The results of analyses of soil samples belonging to various geol.-petrographic formations show a very irregular distribution of Mn. The following classification of the pre-fourth Ice-Age soils of the Kielce voivodship according to the relative Mn content can be given; soils with the highest Mn content (140–7750 mg./kg. of soil on dry-wt. basis) are the light soils on Triassic sandstone, heavy soils on Gottland slate, and on Triassic and third Ice-Age loom, and Devonian and third Ice-Age calciferous carbonate soils. Soils with the lowest Mn content (0–500 mg./kg.) are various soils of noncarbonate formations of the Cambrian and lower Devonian period, light and medium soils of the Triassic sandstone period and middle chalk sandstone period, and light soils of the third Ice-Age gravel-sand period. Soils with medium Mn content are soils on Carboniferous slate, marl-clayey soils of the middle Tura period, calciferous carbonate soils on the Permian, Triassic, Jurassic, and chalk periods, and calciferous gypsum third Ice-Age soils. The rule that the higher content of Mn is present in heavier formations was prevalent in the majority of samples. Richard Ehrlich

STRZEMSKI, M.

Detailed inventory of titanium in Kielce voivodship soils of the pre-fourth-Ice-Age period. M. Strzemski and Z. Gawęda. *Roczniki Nauk Rolniczych* [illegible], 25-41 (1954).—The distribution of Ti in rocks of the pre-fourth Ice-Age period and in soils formed from these rocks in the Kielce voivodship was found to be highly irregular. A definite classification of rock and soil deposits according to Ti content was not possible and only with great difficulty it was possible to distinguish geol.-petrographic groups of soils which are oftener richer in Ti than other groups. Light soils on Ordovian Trias and Lias sandstone, heavier soils on Gottland slate and Trias, and third Ice-Age period loamy soils belong to the groups rich in Ti. The greatest relative accumulation of Ti takes place in soils formed from easily sol. carbonates and gypsum. Ti compds. which are of especially low soly. remain, and show a percentage content which increases at the expense of carbonate and sulfate substances washed out by water. In respect to the distribution of Ti in soil profiles, the soils of the Polish climatic area can be classified according to the following categories: medium and slightly humus soils, poor in Ti and accumulating this element in the humus stratum; medium and slightly humus soils nonpodzolized, in general rich in Ti, not showing accumulation of Ti in any of the profile strata; highly humus soils, nonpodzolized; and litter podzols with various total Ti content accumulating Ti in the humus level. Podzol soils poor in Ti, showing a tendency to accumulate Ti in the underbrush-litter and partially illuvial stratum.

Abstract: Czarnomski was a professor of agriculture and plant growing at Krakow University. His most significant work was "Soil, Its Origin and Types", published in 1900 in Krakow, in which the contemporary knowledge of soil science is widely embraced, and the old notions of the German soil scientists are compared with the new tendency in soil science which was formulated in Russia by V.V. Dokuchaev.

Title : The Problem of Impregnating Polish Soils with Sulfur

Orig Pub: Ekol. Polska, 1956, B2, No 3, 175-181.

Abstract: Polish soils contain infinitestimal quantities of S, explicable by the peculiarities of the natural circumstances of the land and in part as a consequence of the extensive system of agriculture. Mineral fertilizers have come into use only recently and in very minute quantities. Indicated are several measures for enriching the tillable soil with sulfur.

Although by greasing truck walls with oils, coal may be prevented from adhering to the walls, the coal still remains frozen. Sprinkling the loaded coal with various oils is ineffective. Good results have been obtained by mixing, in relation to the quantity of coal, 1 per cent of various oils; coal thus treated does not freeze even when exposed for 48 hours in a temperature of -18 to -20° centigrade. The high cost of oil and of the process, however, make this method uneconomical. The most satisfactory results are achieved by the Soviet method of drying coal to such a degree of humidity (safety humidity) that it will not freeze up.

STRZESZEWSKA, M

4415. NEW METHOD OF PHENOL EXTRACTION BY SELECTIVE SOLVENTS FROM COAL TARS. Kowalski, J. and Strzeszewska, M. (Przem Inst. Min. Hutn. (Centr. Inst. Min. Smelt., Poland), 1955, Vol. 8, 193-205; abstr. in Chem. Abstr., 1957, Vol. 51, 4680, 4681). Phenols can be extracted from coal tars by selective solvents by addition of assisting solvents such as aliphatic hydrocarbons, naphthenes, or their mixtures. These assisting solvents are added to the mixture of coal tars and selective solvents to reduce the solubility of the selective solvents and phenols in coal tars; this causes a separation of two liquid phases. This method is also suitable for extraction of phenols from other oils.

Strzeszewski W., Rose F. Technical and Economical Analysis of Coal Getting by Various Methods.

„Techniczna i ekonomiczna analiza prowadzenia wyrobisk eksploatacyjnych przy różnych systemach eksploatacji". (Prace Gł. Inst. Górn. No. 168), Stalinogród, 1955, Wydawn. Górn-Hut., 48 pp., 32 figs., 41 tabs.

Technical and economic documentary evidence is here collected for 28 longwalls and 20 shortwalls. A comparative list of technical and economical indices for the working tested has been prepared, with special reference to the degree of utilisation of the machinery. On the basis of that material, an analysis is made of the results obtained by various working methods (caving, strip packing and hydraulic stowing) and in different geological and mining conditions, again taking into special consideration the degree of mechanization. A comparative analysis is given as between the results from longwalls and those from shortwalls. Differences in output and in costs depending on the working systems used, on the length of walls, the height of chambers, and the degree of mechanization are shown in terms of figures. The influence on output and costs of various factors — such as, for instance, the work organisation, the utilisation of machines, the degree of training of the personel, and the conditions of work — are also discussed.

Strzetelski J., Szymański J. **Logging Petroleum Wells by Means of Gamma Particles.**

„Profilowanie gamma odwiertów naftowych". (Prace Inst. Naft. No 34), Stalinogród, 1954, WGII, 6 pp., 6 figs.

Radioactivity investigations have been carried out in Poland by the Petroleum Institute in collaboration with the Physics Department of the Mining Academy (Academy of Mines and Metallurgy, Kraków). As a result of these investigations, certain changes in apparatus construction and schema were introduced, changes which secured proper performance of the apparatus in field conditions. In addition a sounding of 80 mm diameter was constructed for measurements of radioactivity in deep wells, and its action examined. The principles interpreting gamma-logging give the main rules for deciphering the results obtained in well-measurements. The experimental data were taken for that purpose partly from the authors' own experiments and partly from foreign literature. As examples of interpretation and application of gamma-logging to geological purposes, the results obtained in measuring various wells are given and correlated to other geological data. Attention is drawn to the possibilities of using other logging methods (e.g. Schlumberger's method, neutron-particle log) for interpreting radioactivity measurements.

Title: Results and Interpretation of Experimental Geochemical Investigations

Original Periodical: Wyniki i interpretacja doswiadczalnych badan geochemicznych, Prace Inst. naftow, 1955, A, No 40, 9-20; Polish; Russian, English, and French resumés

Abstract: Considered are the results of geochemical investigations on 2 territories of Poland located within different geological areas: the first known as concerns petroleum deposits (northern boundary of Carpathian depression), the second, unknown (at the boundary of Nadnidziany and Lodz synclines). As a result of the investigations there has been ascertained a correlation between deposits and geochemical indexes at the earth's surface. The indexes are subdivided

Poland/Cosmochemistry - Geochemistry. Hydrochemistry, D

Abst Journal: Referat Zhur - Khimiya, No 19, 1956, 61291

Abstract: into direct and indirect. Direct indexes: (a) bituminosity; (b) gases and gaseous hydrocarbons dissolved in surface waters, free and adsorbed by rocks; (c) natural radioactivity. Indirect indexes: (a) hydroehemical survey, (b) secondary mineralization, etc. The values obtained for bituminosity, content of gases and radioactivity in the region of geochemical anomalies and background made it possible to determine the magnitude of coefficients for each index (k = anomaly/background), which characterize the presence of anomalies and the probability of petroleum bearing nature of the area.
